Abstract: Properties of the Bi-surplus superconducting $\text{Bi}_{2.1-x}\text{Pb}_x\text{Sr}_2\text{Ca}_2\text{Cu}_3\text{O}_y$ ($x = 0.00-0.60$) compounds have been investigated. It is found that Pb plays a very important role in the formation of the superconducting phases with high purity and especially in promoting and enhancing the stability of the 2223 phase in (Bi,Pb)-Sr-Ca-Cu-O compounds. By increasing the duration of the heat treatment, the single-phase region will be widened, while the transition temperatures and values of zero-resistance remain nearly unchanged. With suitable heat treatment, the 120 K high- T_C phase can be synthesized by the solid-state reaction method. The superconducting fraction reaches a maximum in the compounds with $x = 0.30-0.60$. Special attention is paid that the superconducting state is destroyed by annealing in vacuum for the compound with $x = 0.40$. ?? 2003 Elsevier Science B.V. All rights reserved.
